PRIORITY DOCUMENT

SUBMITTED OR TRANSMITTED IN
COMPLIANCE WITH RULE 17.1(a) OR (b)

4

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

I also certify that the attached copy of the request for grant of a Patent (Form 1/77) bears an amendment, effected by this office, following a request by the applicant and agreed to by the Comptroller-General.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 01645 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

TRANSGENIC ANIMALS AS MODELS
FOR NEURODEGENERATIVE DISEASE

5 The present invention relates to cell and animal
models for a disease condition and in particular to
~~animal models which can function as a model for~~
neurodegenerative diseases, such as Alzheimers.

10 Alzheimers disease is a neurodegenerative disorder
which is the most prevalent form of senile dementia,
with approximately 5% of individuals of 65 and 20% of
~~those over so being afflicted. The disease is~~
characterised by the appearance of two principal
lesions within the brain termed neurofibrillary
15 tangles and senile plaques.

Neurofibrillary tangles are intracellular inclusion
bodies which comprise filamentous aggregates of paired
helical filaments (PHF). The principal component of
20 PHF has been shown to be Tau, a microtubule associated
protein involved in stabilising the cytoskeleton and
in determining neuronal shape. Tau is a
phosphoprotein and aberrant hyper phosphorylation of
Tau appears to represent one mechanism for its
25 aggregation into PHF. Biochemical analysis and
structural prediction of the phosphorylation sites of
human protein Tau of paired helical filaments (PHF) in
brain of Alzheimer's disease (AD) patients revealed
that many sites consist of serine or threonine
30 residues followed by a proline residue, focussing
attention on proline dependent kinases (Wood et al.,
1986; Wischik et al., 1988; Brion et al., 1991;
Hasegawa et al., 1992; Pollanen et al., 1997).

35 Further neurodegenerative disorders mediated by Tau

positive filamentous lesions include, FTDP-17 (Fronto-temporal dementia associated with Parkinson's disease), Cortico-basal degeneration, progressive supranuclear palsy, multiple system atrophy, Pick's disease, Dementia Pugilistica, Dementia with tangles
5 ~~only, dementia with tangles and calcification, Down~~
syndrome, Myotonic dystrophy, Niemann Pick's disease type C, Parkinsonism-dementia complex of Guam, Postencephalic Parkinsonism, Prion diseases with
10 tangles, subacute sclerosing panencephalitis.

~~Despite the data currently available, convincing~~
evidence in addition to a suitable animal model demonstrating and exhibiting the phosphorylation of
15 protein Tau by human kinases *in vivo*, is lacking.

The present invention is therefore directed to providing an animal model of neurodegenerative diseases, such as Alzheimers and which model may be
20 utilised to identify compounds useful in treating or ameliorating the symptoms of the condition.

In a first aspect the present invention provides a nucleic acid vector comprising a) a nucleic acid
25 sequence encoding a human Tau protein; b) a sequence capable of directing expression of said Tau protein in the nervous system of said animal; and c) a sequence which facilitates integration of said vector into the genome of said animal so as to prevent functional
30 expression of said animal Tau protein in favour of said human Tau protein. This construct or vector thus permits generation of cells or non human animals which express the human Tau and which are uncontaminated with endogenous Tau proteins from the
35 animal or cell. Thus, such a cell or non-human animal

may be particularly useful as a model to monitor the function of human Tau proteins and its potential role in the progression of neurodegenerative disorders mediated by Tau protein, such as Alzheimer's disease.

25

30

35

In one embodiment of the invention, the sequence which facilitates integration of the vector into the genome comprises a sequence of nucleotides which exhibits a sufficient degree of homology with the Tau sequence of the animal or the flanking regions thereof, to permit homologous recombination and subsequent insertion of the vector into the genome of said animal at a location which disrupts the coding region and hence expression of the endogenous Tau in said animal in favour of the human Tau protein encoded from the sequence present on said vector. Whilst it will be appreciated by the skilled practitioner that a range of sites upstream, downstream or within the endogenous Tau sequence in the animal genome may be utilised as the site of homologous recombination, it is preferred that the region of homology is selected such that expression of proteins from other gene coding sequences upstream or downstream of the endogenous Tau sequence are not affected. As discussed in more detail in the example below, the vector of the invention may be targeted to, for example, the corresponding Tau sequence of a mouse by the inclusion of a NcoI restriction fragment suitable for insertion of the vector into the unique NcoI site in exon 1 of the Tau sequence in the mouse genome, although as aforementioned a range of appropriate regions of homology to sites upstream or downstream of said Tau sequence may be used.

The vector according to the invention is termed a

"knock in-knock out" vector by virtue of the fact that the endogenous Tau protein is prevented from being expressed in favour of the exogenous DNA sequence. Preferably, such a vector further comprises a marker sequence which in one embodiment may comprise the hygromycin marker gene Pgk-hyg.

10 The sequence encoding the Tau protein is preferably a cDNA sequence, and even more preferably encodes one of the Tau 40 isoforms already known in the art (Goedert M, Trends Neuroscience 1993 Nov; 16(11): 460-465).

15 However, although the known sequences encoding human Tau isoforms may be utilised, mutated Tau sequences may be used to investigate the role of Tau protein in the pathology of neurodegenerative disorders in an animal mediated by Tau protein.

20 A second aspect of the invention comprises a further nucleic acid vector comprising (a) a nucleic acid sequence encoding a protein capable of modulating a human Tau protein; (b) a sequence capable of directing expression of said protein in the cells of said animal; and (c) a targeting sequence capable of facilitating integration of said vector into the genome of said animal optionally at a position corresponding to a sequence in said animal equivalent to said protein capable of modulating human Tau protein, so as to prevent expression of said equivalent sequence in favour of said protein capable of modulating human Tau protein.

30

Such a vector when integrated at said equivalent sequence in the animal genome, in a similar fashion to the vector described above, permits expression of the protein capable of modulating Tau protein in favour of

35

the related or equivalent protein in said animal.

The sequence capable of directing expression of said human Tau protein or the modulator thereof is preferably a transcriptional control sequence which
~~can steer expression of the proteins to the nervous~~
system of the non-human animal. Transcriptional control sequences according to the invention comprise a suitable promoter and other regulatory regions, such
as enhancer sequences, that can modulate the activity of the promoter.

A promoter refers to the region of DNA that is upstream with respect to the direction of transcription of the transcription initiation site and which promoter is in a relationship permitting expression of the relevant proteins according to the invention.

DNA sequences that drive expression to neurons are known. They include both control systems that are neuron-specific and control systems that are more or less promiscuous but that induce high levels of expression in neurons. Depending on the nature of the construct used in the production of the transgenic animal and, in particular, the control elements, the desired proteins may be expressed in all neurons or only in restricted subsets of neurons of transgenic animals. Neuron-specific control systems, that drive expression to neuronal cell types in general, are known. They may be derived from genes encoding neuron-specific proteins. Such systems may be used to bring about expression of the desired Tau protein and/or the protein capable of it's modulation, in neurons.

Preferably the sequence is a promoter which directs expression of said proteins in the neurons of the brain or other such cells including astrocytes, oligodendrocytes microglia or Schwann cells.

5 Preferably, the promoter is the mouse Thy-1 promoter
~~which drives expression in mouse central neurons.~~

10 The vector according to this aspect of the invention may, advantageously, be used in combination with the vector incorporating the sequence encoding the human Tau protein described above to transfect a non-human
~~animal and thus provide a transgenic animal which~~
serves as a model permitting investigation into the interactions between the protein capable of modulating
15 human Tau protein and said Tau protein and identification of potential therapeutic agents capable of modulating the effects of the phosphorylation of Tau.

20 Alternatively, a transgenic animal incorporating the nucleic acid vector encoding said human Tau protein may be crossed with another transgenic animal comprising the vector encoding said protein capable of modulating human Tau protein which may result in
25 offspring which express both of the proteins.

The human sequences introduced into the transgenic animals may encode those which are known in the art. Preferably, the human Tau comprises a human Tau
30 isoform already known in the art. Alternatively, the sequence may have been subject to a mutation, such as for example, a point mutation which may simulate a mutation that gives rise to certain genetic diseases. There are techniques known in the art to mutate a
35 desired genetic region so as to inactivate or alter

function or expression of the protein. Such techniques include homologous recombination. Methods for detecting homologous recombinant events include the polymerase chain reaction or by using marker or reporter genes which are only expressed in the event of a successful targeted recombinant event. Such mutated sequences when expressed in a transgenic non-human animal can advantageously, be used to investigate their effect on the phenotype of said animal and its role in the progression of neurodegenerative disease, such as Alzheimers mediated by Tau protein.

In a preferred embodiment of the second aspect of the invention, the protein capable of modulating human Tau protein is a kinase, and preferably one which is capable of phosphorylating human Tau protein, such as human GSK-3 β kinase, for example. *In vitro* assays have identified glycogen synthase kinase-3 β (GSK-3 β) as one candidate involved in phosphorylation of Tau. Phosphorylation by GSK-3 β of bovine (Ishiguro et al., 1992a and 1992b) and human protein Tau (Hanger et al., 1992; Mandelkow et al., 1992) in cell-free systems, resulted in phosphorylation patterns of protein Tau that resembled those of the protein isolated from PHF from AD brain (Ishiguro et al., 1993). The *in vitro* phosphorylation of human recombinant protein Tau by GSK-3 β reduced its ability to induce microtubule nucleation (Utton et al., 1997), while the kinase also phosphorylated neurofilament proteins on specific domains (Guan et al., 1991). Further evidence for GSK-3 β as a potential protein Tau and neurofilament kinase has been obtained in transfected cells, wherein both protein Tau (Lovestone et al., 1994; Anderton et al., 1995; Lovestone et al., 1996; Lovestone and Reynolds,

1997) and NF-H were identified as substrates. Co-transfection of GSK-3 β with Tau in CHO cells increased its phosphorylation concomitant with loss of prominent bundles of microtubules (Wagner et al., 1996), while
5 co-transfection with NF-H in COS cells caused
~~electrophoretic mobility retardation and the~~
appearance of phosphate-dependent antibody profiles.

The involvement of GSK-3 β in the hyperphosphorylation
10 of Tau, both in cultured neurons and in vivo in brain,
was indirectly supported by the finding that lithium,
~~as inhibitor of GSK-3 β , caused Tau dephosphorylation~~
at the sites recognized by antibodies Tau-1 and PHF-
1, which are two of the major epitopes typically
15 associated with PHF in AD brain. The physiological
role of GSK-3 β was proposed to be in stabilizing the
neuronal cytoskeleton by controlling phosphorylation
of Tau and neurofilament-H and eventually other
substrates (Takahashi et al., 1994). In addition, GSK-
20 3 β plays a role in the development of the brain of
Xenopus as part of the Wingless signaling pathway in
which the kinase is a negative regulator of
dorsoventral axis formation. In this mechanism,
phosphorylation of β -catenin, mediated by axin or
25 conductin, controls the degradation of β -catenin by
the ubiquitin-proteasome pathway (Aberle et al., 1997;
Behrens et al. 1998; Ikeda et al., 1998). Thus, the
model is particularly useful to investigate the
molecular basis for Alzheimers and other
30 neurodegenerative disorders mediated by Tau protein
and to investigate compounds which may alleviate the
symptoms of the disease.

The vectors may be transformed into a suitable host
35 cell which is preferably eukaryotic, which may itself

be used to transform a non-human animal. Thus, in a further aspect the invention provides a process for preparing human Tau protein or a protein capable of modulating Tau protein, comprising cultivating a host
5 cell transformed or transfected with a vector

~~according to the invention, under conditions to~~
provide for expression by the vector of said proteins, and recovering the expressed proteins. Preferably, the host cell is a non-human animal cell, and even
10 more preferably, an embryonic cell of a non-human animal.

Incorporation of the nucleic acid sequences into the vector according to the invention for subsequent
15 transformation and integration into the genome of said host cell or non-human animal is carried out by procedures well known to those skilled in the art as provided in Sambrook et al., Molecular Cloning, A Laboratory Manual, Cold Spring Harbour Laboratory
20 Press. The vector may be introduced by transfection or other suitable techniques such as electroporation. In the present invention, the incorporation of the exogenous DNA into the genome of the animal is accomplished by electroporation of the vector in
25 embryonic stem cells. The cells that have the exogenous DNA incorporated into their genome by homologous recombination may subsequently be injected into blastocysts for generation of the transgenic animals with the desired phenotype. Successfully
30 transformed cells which contain the vector according to the invention may be identified by well known techniques, such as lysing the cells and examining the DNA by, for example, Southern blotting or using the polymerase chain reaction.

The vectors may be, for example, plasmid, virus, cosmid or phage vectors, and may contain one or more selectable markers such as the hygromycin marker gene P_{gk}-hyg.

5

The present invention also advantageously provides nucleic acid sequences of at least approximately 10 contiguous nucleotides of a nucleic acid according to the invention and preferably from 10 to 50 nucleotides even more preferably, the nucleic acid sequence
10 comprise the sequences illustrated in Table 1. These sequences may, advantageously be used as probes or

primers to initiate replication, or the like. Such nucleic acid sequences may be produced according to
15 techniques well known in the art, such as by recombinant or synthetic means. They may also be used in diagnostic kits or the like for detecting the presence of a nucleic acid according to the invention. These tests generally comprise contacting the probe
20 with the sample under hybridising conditions and detecting for the presence of any duplex or triplex formation between the probe and any nucleic acid in the sample.

25 The probes according to this aspect of the invention may be anchored to a solid support. Preferably, they are present on an array so that multiple probes can simultaneously hybridize to a single biological sample. The probes can be spotted onto the array or
30 synthesised *in situ* on the array. (See Lockhart et al., Nature Biotechnology, vol. 14, December 1996 "Expression monitoring by hybridisation to high density oligonucleotide arrays". A single array can contain more than 100, 500 or even 1,000 different
35 probes in discrete locations.

The nucleic acid sequences, according to the invention may be produced using such recombinant or synthetic means, such as for example using PCR cloning mechanisms which generally involve making a pair of
5 primers, which may be from approximately 10 to 50 nucleotides to a region of the gene which is desired
to be cloned, bringing the primers into contact with mRNA, cDNA, or genomic DNA from a human cell, performing a polymerase chain reaction under
10 conditions which bring about amplification of the desired region, isolating the amplified region or fragment and recovering the amplified DNA. Generally,
such techniques are well known in the art, such as described in Sambrook et al. (Molecular Cloning: a
15 Laboratory Manual, 1989).

The nucleic acids or oligonucleotides according to the invention may carry a revealing label. Suitable labels include radioisotopes such as ^{32}P or ^{35}S , enzyme
20 labels or other protein labels such as biotin or fluorescent markers. Such labels may be added to the nucleic acids or oligonucleotides of the invention and may be detected using known techniques per se.

Antisense technology can be used to control gene
25 expression through triple-helix formation of antisense DNA or RNA, both of which methods are based on binding of a polynucleotide to DNA or RNA. For example, the 5' coding portion or the mature protein sequence,
30 which encodes for the protein of the present invention, is used to design an antisense RNA oligonucleotide of from 10 to 50 base pairs in length. A DNA oligonucleotide is designed to be complementary to a region of the gene involved in transcription
35 (triple-helix - see Lee et al. Nucl. Acids Res.,

6:3073 (1979); Cooney et al., Science, 241:456 (1988);
and Dervan et al., Science, 251: 1360 (1991), thereby
preventing transcription and the production of human
Tau or the protein capable of modulating Tau according
5 to the invention defined herein. The antisense RNA
oligonucleotide hybridises to the mRNA *in vivo* and
blocks translation of an mRNA molecule (antisense -
Okano, J. Neurochem., 56:560 (1991);
Oligodeoxynucleotides as Antisense Inhibitors of Gene
10 Expression, CRC Press, Boca Raton, FL (1988)).

Thus advantageously the expression of each of the
relevant proteins may be inhibited using antisense
technology which may be used to selectively confirm
15 the action of candidate compounds which may be
identified as potential treatments for Alzheimers or
other neurodegenerative diseases mediated by Tau
protein using the transgenic non-human animal
described herein, which expresses said human Tau
20 and/or said protein capable of modulating human Tau
protein.

Recently it has become possible to manipulate the
expression of genes in animals by engineering genetic
25 switches in the genome of the animal which can be
designed to target expression or ablation of any gene
to any tissue at any defined time. (Inducible gene
targeting in mice using the Cre/lox system, a
companion to methods in enzymology 14, 381-392 (1998).
30 Using this technology expression of any of the
proteins according to the invention can be
manipulated, for example, such that expression only
occurs when the transgenic line has been established.
Accordingly, the vectors of the invention may include
35 a stop signal or sequence between the sequence capable

of directing expression of said human Tau or the protein capable of modulating human Tau protein, which stop signal is flanked by two loxP sites. When the vector is used to establish the transgenic line as described above and in the examples below, expression
5 ~~of the relevant protein will not occur unless the Cre~~
recombinase protein is present. The Cre protein catalyses reciprocal conservative DNA recombination between the pairs of loxP sites with the resulting
10 excision of the stop sequence located between the loxP sites. The Cre protein may itself be expressed in
~~another transgenic animal which is mated with the~~
first, to remove the stop sequence following the reciprocal combination event between the two loxP
15 sites to switch on expression of the appropriate sequence in the transgenic animal. This technique also permits the DNA sequence encoding the proteins according to the invention to be excised by the Cre protein by including in the appropriate nucleic acid
20 vector loxP sites flanking the sequences encoding human Tau and/or the protein capable of modulating human Tau protein. Such vectors can be used to investigate the role of null mutations or knock-outs of the sequences encoding the proteins in the
25 transgenic animal according to the invention.

In accordance with the present invention, a defined nucleic acid includes not only the identical nucleic acid but also any minor base variations including in
30 particular, substitutions in cases which result in such as for example a synonymous codon (a different codon specifying the same amino acid residue) due to the degenerate code in conservative amino acid substitutions. The term "nucleic acid sequence" also
35 includes the complementary sequence to any single

stranded sequence given regarding base variations.

A further aspect of the invention comprises a method of making a transgenic non-human animal which
5 expresses a human Tau protein comprising the steps of:

(a) introducing into an embryo cell of said animal a
nucleic acid vector according to the invention; (b)
introducing the embryo from step (a) into a female
animal; (c) sustaining the female in step (b) until
10 such time as the embryo has sufficiently developed and
is borne from the female; and (d) sustaining the
transgenic animal.

A further method of generating a transgenic non-human
15 animal which expresses a human Tau protein comprises
the steps of (a) introducing sequentially or
simultaneously into an embryo cell of said animal a
nucleic acid vector comprising a transgene encoding
said human Tau protein; and a nucleic acid vector
20 comprising a sequence of nucleotides which upon
integration into the genome of said animal are capable
of preventing expression of endogenous Tau protein
from said animal; (b) introducing the embryo from step
(a) into a female animal; (c) sustaining the female in
25 step (b) until such time as the embryo has
sufficiently developed and is borne from the female;
and (d) sustaining the transgenic animal.

Another method of generating a transgenic non-human
30 animal which is a model for diseases such as
Alzheimers disease, comprises crossing a first
transgenic non-human animal expressing human Tau
protein from a vector according to the invention with
a second transgenic non-human animal expressing a
35 protein capable of modulating human Tau protein

according to the invention, selecting among the progeny those that carry both expression of said human Tau protein and said protein capable of modulating human Tau protein.

5

As described above, the Cre/lox technology can be used to manipulate expression of the proteins in each of the transgenic non-human animals described herein by incorporation of loxP sites flanking an appropriate DNA sequence. The sequences may be those encoding human Tau or the protein capable of modulating human Tau protein themselves or a stop sequence or codon which prevents expression of the above proteins unless a recombination event occurs in the presence of Cre recombinase to remove the stop sequence.

10
15

A further aspect of the invention comprises a transgenic non-human animal that is a model for Alzheimers disease or for another neurodegenerative disease, which animal comprises an introduced DNA sequence encoding and capable of expressing the protein Tau in the nervous system of said animal and also comprises a DNA sequence encoding and capable of expressing a protein capable directly or indirectly of modulating the human Tau protein. In this aspect of the invention the human Tau and the protein capable of modulating human Tau are preferably those encoded by the sequences on the vectors according to the invention as described above.

20
25
30

A further aspect of the invention comprises a method of generating a transgenic non-human animal which is a model for Alzheimers disease or related neurodegenerative disorders, comprising the steps of crossing a first transgenic non-human animal

35

comprising a vector having, i) a nucleic acid sequence
encoding a human Tau protein, ii) a sequence capable
of directing expression of said human Tau protein in
the nervous system of said animal and iii) a targeting
5 sequence which facilitates integration of said vector
into the genome of said animal, with a second
transgenic non-human animal comprising a vector
capable of expressing a protein capable of modulating
human Tau protein according to the invention,
10 selecting among the progeny those that express both
human Tau protein and said protein capable of
modulating human Tau protein.

Another transgenic non-human animal according to the
15 invention is also provided by crossing a first
transgenic non-human animal expressing human Tau
protein with another non-human animal transgenic for
the protein which modulates human Tau protein.
Therefore, according to this aspect of the invention
20 there is provided a method of generating a transgenic
non-human animal which is a model for Alzheimers
disease or related neurodegenerative disorders,
comprising the steps of crossing a first transgenic
non-human animal comprising a vector having, i) a
25 nucleic acid sequence encoding a human Tau protein,
ii) a sequence capable of directing expression of said
human Tau protein in the nervous system of said animal
and iii) a targeting sequence which facilitates
integration of said vector into the genome of said
30 animal, with a second transgenic non-human animal
comprising a vector according to the invention,
selecting among the progeny those that express both
human Tau protein and said protein capable of
modulating Tau protein.

The term "progeny" or "offspring" is intended to include the resulting product of a mating between the transgenic animals described provided it carries a vector according to the invention. Also included are
5 germ cells from said transgenic animals which may

~~themselves be used to produce further offspring~~
comprising a vector according to the invention stably integrated into its genome.

10 Preferably, the non-human animal used in accordance with the methods of the invention is a mammal and even

more preferably a mouse.

The nucleic acid vectors described can be introduced
15 into the embryonic stem cells, by for example electroporation. Microinjection of the cells is performed on the embryo when it is at the one cell stage, thus ensuring that the nucleic acid vector will be incorporated into the germ line of the animal and
20 thus be expressed in all cells of the animals and subsequent transmission to progeny. A further aspect of the invention comprises progeny of the transgenic animal according to the invention, which progeny carries any of the nucleic acid vectors according to
25 the invention stably integrated into their genome.

The transgenic animal may advantageously exhibit the symptoms of Alzheimer's or other related neurodegenerative disorders mediated by human Tau
30 protein phosphorylation making it a suitable model for the disease in humans. Compounds which modulate (either by enhancing or inhibiting) the hyperphosphorylation of human Tau protein may be identified by administering the compounds to the
35 animal. Compounds identified as enhancers may

advantageously be applied to the animal to enhance development of the disease. Inhibitors of the disease may be identified by monitoring the effects or the phosphorylation profile of Tau protein in the animal following application or administration of the compound to the animal. The compounds may be administered by any suitable route, such as orally or intravenously.

It will be appreciated that not every vector, which may otherwise be referred to as a transgene, will function optimally in every cell or animal type. Thus, routine experimentation may be required to identify or establish the best kinase or Tau isoform or promoter sequence for any given cell or animal type. Antibodies to the protein or polypeptide of the present invention may, advantageously, be prepared by techniques which are known in the art. For example, polyclonal antibodies may be prepared by inoculating a host animal, such as a mouse, with the polypeptide according to the invention or an epitope thereof and recovering immune serum. Monoclonal antibodies may be prepared according to known techniques such as described by Kohler R. and Milstein C., Nature (1975) 256, 495-497. Advantageously, such antibodies may be included in a kit for identifying the human Tau of the kinase in a sample, together with means for contacting the antibody with the sample.

The invention may be more clearly understood from the following exemplary embodiment by reference to the accompanying Figures wherein;

Figure 1: is an illustration of the recombinant DNA construct used to target the mouse

Tau locus. The triangles represent the loxP sites. The black boxes indicate a part of the exon 1 of the mouse Tau gene. BSSK+ denotes the bluescript cloning vector. P_{gk}-hyg represents the hygromycin marker gene. The middle

figure shows a partial structure of the wild-type mouse Tau gene. Nco 1 is the unique site on exon 1 into which the entire construct is introduced. The lower figure shows the construct ready for introduction into the ES cells and

if homologous recombination occurs in the mouse genome, the different probes used with different enzyme digestions. Details are in the text under the section.

Figure 2: is an illustration of the Southern Blot used to identify transgenic mice incorporating the human Tau 40 cDNA at the embryonic stage. 5 of the 46 pups injected at the embryonic stage contained the DNA.

Figure 3: is an illustration of a Western Blot results indicating a 70 kDa Tau protein in three different transgenic mouse strains, and probed with antibodies HT-7 and Tau-5.

Figures 4 & 5: are illustrations of the different digestions using rare cutting restriction enzymes in a restriction map of the human Tau gene.

Figure 6: is an illustration of the expression of human GSK-3 β in brain of transgenic mice.

5 Figure 7: is an illustration of the results of a Western Blot of brain extracts of GSK-3 β [S9A]/htau40 double transgenic mice, 5 weeks old. Brain extracts from wild-type (WT), GSK-3 β [S9A] single
10 transgenic ([S9A]-5), htau40 single transgenic and GSK-3 β [S9A]/htau40 double transgenic mice were
immunoblotted with the specified monoclonal antibodies. For Tau-5
15 immunodetection, 6 times less extract was applied than for AT8 and AT-180 staining. Intense hyperphosphorylation of human protein tau was evident by
reaction with monoclonal antibodies AT-
20 8 and AT-180 in the double transgenic animals of all three lines generated. Relative Mr is indicated on the left in kDa. The single and double accolades on the right denote the endogenous
25 murine and the transgenic human protein tau respectively.

Figure 8: is an illustration of the method of producing the loxP - hygromycin
30 construct.

restriction enzymes.

Figure 10: illustrates a restriction map of the construct of Figure 8.

5 Figure 11: is an illustration of the results obtained by probing a cell line to ensure the presence of the constructs

10 Figure 12: is an illustration of Western Blotting of brain extracts of GSK-3 β [S9A] transgenic mice of 7 months old. Each panel compares brain extracts from 2 individual wild type (wt) mice and from

15 2 individual GSK-3 β [S9A] transgenic mice, all about 7 months old, immunoblotted with antibodies Tau-5, PHF-1, AT-8 and AT180 as indicated with each panel. Brain homogenates were purified from mouse IgG prior to electrophoresis.

20 Figure 13: is an illustration of the effect of alkaline phosphatase pretreatment on hyperphosphorylated protein tau. Brain homogenates of single and double htau-40-5 and GSK-3 β [S9A]/htau40 transgenic mice were either applied untreated, or after incubation at 37°C for 3 hours without or with alkaline phosphatase (0.5 unites per μ l) prior to Wester

25 Blotting. For staining with antibodies Tau-5 and Tau-1, the amounts of extract applied were 6 times less than for blotting with AT-8 and AT-180. Note the reduction in signals and the

30 increase in electrophoretic mobility as

35

described and discussed in the text.

Transgenic GSK-3 β [S9A] mice

5 Five independent transgenic founders were generated
that contained the human GSK-3 β [S9A] mutant kinase
under the control of the mouse thy-1 gene promoter, in
the FVB genetic background. All experiments were
comparatively performed with heterozygous mice from
10 lines GS-3 β [S9A]-5 and -1 in which GSK-3 β expression
was highest and which were concordant in all
phenotypic aspects.

The human GSK-3 β protein was revealed by Western
15 Blotting (Fig 6A) and was enzymatically active towards
a GS-1 synthetic peptide. In brain homogenates of
transgenic mice, GSK-3 β kinase activity was about
doubled relative to the activity in wild-type mouse
brain (Fig 6B). Immunohistochemically, the human
20 protein was localized in neuronal cell bodies and in
processes in the cortex and hippocampus conform to and
expected from the known expression pattern of the
adapted mouse thy1 gene construct used (Moechars et
al., 1996 and references therein).

25

Transgenic human tau40 mice

Five independent transgenic founders were generated
that contained the human tau40 cDNA, embedded in the
30 adapted mouse thy-1 gene promoter; similar to the
construct used above. Three founder lines, i.e.
htau40-1, -2 and -5 transmitted the transgene in a
mendelian pattern and were analyzed. Western Blotting
with the human specific phosphorylation-independent
35 monoclonal antibody HT-7 demonstrated highest

expression of human protein tau in lines htau40-1 and htau40-2 (Fig 3A). Western blots of total protein tau with the phosphorylation-independent monoclonal antibody Tau-5 were quantified by densitometric scanning to demonstrate that the ratio of transgenic human to endogenous mouse protein tau was about 1.5, 1.6 and 0.5 respectively in the three transgenic lines (Fig 3B). In the brain of human protein tau40 transgenic mice of 4 to 8 weeks old, the antibody HT-7 stained the pyramidal nerve cell bodies and their processes in the hippocampus and the cortex (Fig 7C), while strong labelling was also evident in cortical layer V.

15 Analysis of phosphorylation of protein tau

Extensive analysis was performed by Western Blotting of mouse brain extracts with a battery of well-characterised antibodies including antibodies specific for different epitopes of protein tau known to be phosphorylated by GSK-3 β (Sperber et al., 1995). In GSK-3 β [S9A] transgenic mice, 4-8 weeks old, only minor differences in electrophoretic migration was observed relative to age-matched wild-type mice and analyzed by Western Blotting with the PHF-1 antibody. The hyperphosphorylation of murine protein tau in such transgenic animals was evidenced by AT-180 immunoreactivity, but only by longer exposure of the western blots. The additional, and wanted reaction with antibody AT-8 remained, however, absent in the single transgenic mice of less than 2 months old. In the brain of older GSK-3 β transgenic mice, i.e. aged up to 16 months (Fig 12), the immunoreactivity of both phosphorylation-dependent antibodies AT-8 and AT-180 were observed clearly, concomitant with a slower

electrophoretical mobility of the immuno-reactive isoforms of protein tau detected also with monoclonal antibodies Tau-5 and PHF1 (Fig 12).

5 Extensive immuno-histochemical analysis was performed
on both paraffin and on cyrostat sections cut from
brain of mice sacrificed at different ages and
processed and fixed following several different
procedures. Staining with the antibodies used in
10 Western Blotting and with many additional antibodies
failed to reveal appreciable and reproducible
phosphorylation of endogenous mouse protein tau in the
GSK-3 β transgenic mice. It is obvious that human
protein tau is far better characterized than mouse
15 protein tau, and that the antibodies used are
primarily directed to human protein tau. Since,
moreover, evidence for any tau-pathy is lacking in
mice, the present inventors decided to investigate the
role of GSK-3 β in mediating phosphorylation of human
20 protein tau *in vivo*, by generating double transgenic
mice coexpressing human protein tau next to GSK-
3 β [S9A] in the same neurons.

Definite hyper-phosphorylation of human protein tau
25 was demonstrated in brain extracts of these double
transgenic mice, even at the early age of 5 weeks, by
Western Blotting with antibodies AT-8, AT-180 and Tau-
5 (Fig 7). Brain of single transgenic littermates
expressing GSK-3 β or human tau40 only, showed no or
30 much weaker AT-8 and AT-180 immunoreactivity and
contained no or much less of the slower migrating
isoforms of protein tau. Pre-treatment of brain
extracts with alkaline phosphatase prior to
electrophoresis, yielded identical protein tau
35 patterns of all mice on the Western Blots and

abolished AT-8 and AT-180 immunoreactivity of both murine and human protein tau (Fig. 13). In addition, prior de-phosphorylation increased immunoreactivity with antibody Tau-1 (Fig 13).

5

The hypothesis that GSK-3 β is a major kinase capable of hyperphosphorylation of protein tau in brain was first approached and tested in vivo, by overexpression of a constitutively active human kinase, i.e. GSK-3 β [S9A] in the brain of transgenic mice using the mouse thyl gene promoter. The transgene was enzymatically active in brain and expressed mainly in hippocampal and cortical neurons, thereby about doubling the overall GSK-3 β kinase activity. Murine protein tau extracted from the brain of young GSK-3 β [S9A] transgenic mice was somewhat hyperphosphorylated, as manifested by the presence of isoforms with slower electrophoretic migration, with some AT-180 immunoreactivity but weak or absent AT-8 reaction on western blots. In older mice tested at 7 and 16 months of age, endogenous protein tau isoforms with clearly retarded electrophoretic mobility and with strong AT-8 immuno-reactivity were evident in the brain. Isoforms of murine protein tau that migrated on 8% polyacrylamide gels as a broadened band, reacted with antibodies PHF-1 and Tau-5. The increased PHF-1 immunoreactivity caused by GSK-3 β -mediated hyperphosphorylation can be attributed to phosphorylation of serine residues at positions 396 and/or 404 that participate in this epitope (Otvos et al. 1994). *In vitro* studies showed that hyperphosphorylation of these and other epitopes rendered the slower migrating tau isoforms.

35 The reasons to investigate not only endogenous mouse

protein tau but also human protein tau as substrate for GSK-3 β [S9A] in these transgenic mice, are many and not only practical. Evidently, all the typical and specific antibodies used to detect phosphorylated epitopes on protein tau are directed against the human protein. In addition, evidence for any involvement of

endogenous murine protein tau in tau-pathy is lacking. Therefore, the ability of GSK-3 β to mediate phosphorylation of human protein tau was investigated by generating double transgenic mice, i.e. mice that coexpress the human tau40 protein isoform and the human GSK-3 β [S9A] mutant kinase. To this end,

transgenic mice were generated that overexpressed the longest human protein tau isoform, i.e. human protein tau40 containing 2 N-terminal inserts and 4 microtubule binding repeats. Using the same type of gene promoter construct assured the expression of both transgenes to coincide inside the same neurons in brain. In the single and double transgenic mice, human tau protein accounted for up to 60% of total protein tau in the brain of the highest expressing transgenic mouse line.

Immunodetection with HT-7 revealed a somatodendritic localisation in addition to axonal staining, similar to a previous report on human tau transgenic mice (Götz et al. 1995), and resembling the localisation of endogenous protein tau in central neurons (Tashiro et al. 1997).

The cross-breeding yielded the expected numbers of double transgenic mice offspring, which were identified by genotyping and demonstrated by Western Blotting to co-express human protein tau40 and human GSK-3 β [S9A]. In the brain of the double transgenic

mice, unambiguous and robust hyper-phosphorylation of protein tau was evident as early as 5 week-old of age, by the presence of slower migrating isoforms reacting strongly with both antibodies AT-8 and AT-180. This

5 proved that the epitopes of antibody AT-8, involving ~~serine 199 and/or 202 residues and the epitope of~~ antibody AT-180, involving threonine 231, were abundantly phosphorylated, not excluding additional phosphorylation at other residues to induce the slower

10 migrating tau proteins. Tau's binding to microtubules was eliminated by the phosphorylation of several sites ~~(Mandelkow et al. 1995, Trineczek et al. 1995, Preuss~~ et al. 1997), among which residue Thr231 was of major importance (Sengupta et al. 1998). De-phosphorylation

15 prior to electrophoresis destroyed both the AT-8 and AT-180 immunoreactivity, increased the reaction with antibody Tau-1 and increased the electrophoretic mobility of protein tau.

20 The cDNA coding for human GSK-3 β [S9A] (Sutherland et al. 1993; Stambolic and Woodgett, 1994) was ligated in the mouse thyl gene (Moechars et al., 1996). A PvuI-NotI restriction fragment was micro-injected into 0.5 day old FVB/N pre-nuclear mouse embryos. Transgenic

25 founders were identified by southern blotting of StuI-restricted mouse tail-biopsy DNA, hybridized with a probe of 701 bp obtained by PCR with forward primer 5'CAAGGTCCCGTTTCTCC3' and reverse primer 5'CAGGGGATAGTGGTGTGG3'. Routine genotyping of

30 transgenic offspring, bred into the FVB/N genetic background, was performed on tail-biopsy DNA with forward primer 5'CCCCACCACAGAATCCA3' located in the mouse thyl gene and with reverse primer 5'GCTGCCGTCTTGTCTCT3' located in the human GSK-3 β

35 cDNA. Human Tau40 was ligated in the mouse thyl gene.

A PvuI-NotI restriction fragment was micro-injected and transgenic founders identified by southern blotting of StuI-restricted mouse tail-biopsy DNA. The probe of 135 bp was obtained by PCR with forward
5 primer 5'CCCCACCACAGAATCCA3' located in the mouse thyl
~~gene and reverse primer 5'GCCCCCTGATCTTTCC3' located~~
in the human tau40 cDNA. Routine genotyping of transgenic offspring, bred into the FVB/N genetic background, was performed on tail-biopsy DNA by PCR
10 with a forward primer 5'CTGGGGCGGTCAATAAT3' located in the human tau40 gene and a reverse primer
~~5'CAAGGTCCCCCTTTCTCC3' located in the mouse thyl gene,~~
yielding a 213 bp amplicon.

15 GSK-3 β [S9A] protein levels in brain extracts were estimated by Western Blotting with monoclonal antibodies TPK I/GSK-3 β (0.1 μ g/ml) and htau40 protein levels with monoclonal antibodies HT-7 (0.5 μ g/ml) and Tau-5 (0.5 μ g/ml). Kinase enzymatic activity was
20 measured on brain homogenates after immunoprecipitation and fractionation by ion-exchange FPLC (Mono S) (Pharmacia, Uppsala, Sweden) (Van Lint et al. 1993).

25 For immunohistochemistry of brain, mice were anesthetized with nembutal and intracardially perfused with either paraformaldehyde (4% v/v) or methacarn (MC) (50% methanol, 30% chloroform, 10% acetic acid). Brains were immersion-fixed overnight, dehydrated and
30 embedded in paraffin (unless stated otherwise). Microtome sections (6 μ m) were dewaxed, hydrated and incubated with blocking solution, i.e. 3% BSA, 10% normal goat serum in Tris Buffered Saline (TBS) (50 mM Tris, pH7.4, 0.15 M NaCl). Incubation was for 12
35 hours with primary antibodies and for 1 hr with biotin

conjugated secondary antiserum in blocking solution, and immunoreactivity was intensified with the Strep-ABComplex/HRP system (Dako A/S, Denmark). A monoclonal antibody to MAP2 (1/400) was used to mark
5 dendrites.

For immunohistochemical detection of human tau in the htau40 transgenic mice, paraformaldehyde (4% in PBS) fixed free-floating vibratome slices (40 μ m) were
10 subsequently incubated with 300 μ l blocking solution (see above) for one hour and overnight with 250-300 μ l
~~primary antibody (HT-7, 2.5 μ g/ml; AT-8, 2.5 μ g/ml;~~
AT-8, 2.5 μ g/ml; PHF-1, 1/50) in blocking solution in
a 24 well Costar cell culture plate. Next, brain
15 sections were rinsed with 500 μ l TBS (3x5'), incubated with biotin conjugated secondary antibody (1/1000) for one hour, washed (3x5') and pretreated with 500 μ l 0.05 M Tris-HCl for 5 minutes. These tissue sections were submerged in 300 μ l Strept-ABComplex/HRP (1
20 droplet of both solutions per 15 ml 0.05 M Tris-HCl) for half an hour and successively washed (3x5'), pretreated with 500 μ l 0.05 M Tris-HCl for 5' and stained with DAB.

25 For Western Blotting, brain tissue was homogenized in 2 ml of MES buffer with inhibitors, i.e. 0.1 M MES (pH 6.4), 0.5 mM MgCl₂, 1 mM EDTA, 1 mM EGTA, 1 mM DTT, 5 μ g/ml leupeptin, 5 μ g/ml pepstain, 1 μ M okadaic acid, 200 μ M PMSF, 20 mM NaF, 200 μ M sodium orthovanadate, 5
30 μ g/ml soybean trypsin inhibitor, 1% Triton-X-100, 1% sodium desoxycholate and 0.1% SDS. After centrifugation (100,000 g for 30' at 4°C), portions of the supernatant were denatured and reduced prior to separation on Tris-glycine buffered polyacrylamide
35 gels (8% SDS-PAGE) (Novex, San Diego, CA) and

transferred to nitrocellulose filters. Following antibodies were used: monoclonal AT-8 and AT-180 (1 μ g/ml), PHF1 (1/25) and Tau-5 (1 μ g/ml). Signals were quantified by densitometry and normalized to signals obtained on the same blots with phosphate-independent antibody Tau-5.

Since mouse immunoglobulins interfere with the AT-8 and AT-180 immunoreactivity on Western Blotting (~50kDa), brain homogenates of GSK-3 β transgenic mice were incubated with immobilized protein-G (Pierce, Illinois, USA) at 4°C for 2.5 hours and purified from mouse IgG by centrifugation (8000 rpm, 5', 4°C). The supernatant was denatured and reduced prior electrophoretical separation.

To dephosphorylate the tau protein, brain homogenates were diluted in a dephosphorylation buffer (Boehringer Mannheim) containing alkaline phosphatase (Boehringer Mannheim, 0.5 unit/ μ l homogenate) and gently stirred at 37°C for 3 hours. Samples to be loaded on the gel were prepared as mentioned above.

Antibodies HT-7 (directed to human tau), AT-8 (directed to phosphorylated Ser199 and/or Ser202 (Biernat et al. 1992) and AT-180 (directed to phosphorylated Thr231 (Goedert et al. 1994) are purchased from Innogenetics, Gent, Belgium. Anti-TPKI/ GSK-3 β was bought from Affinity, Nottingham, UK; Tau-5 (recognizing tau, phosphate-independent) from Beckton Dickinson, San Diego, CA; Tau-1 (directed to non-phosphorylated Ser199 and Ser202 (Biernat et al. 1992) from Boehringer Mannheim, Germany and biotin conjugated secondary antiserum from Biorad Labs, CA. PHF1 (directed to phosphorylated Ser396 and Ser404

(Otvos et al. 1994) was a gift of P. Davies.

Synthesis of the construct to target the mouse Tau locus

5

~~A 1.9 kb Not I fragment encoding the 3' loxP and the~~
Hygromycin B phosphotransferase gene driven by the
phosphoglycerate kinase (PGK promoter) was first
cloned into the BamHI site of the pBluescript vector.
10 Secondly, a 8 kb Mlu I β Aat II fragment containing the
human Tau cDNA coding for the longest isoform of human
~~adult Tau driven by the mouse Thy I promoter was cut~~
out together with a 5' loxP site from the pGEM lox
vector and subcloned into the SmaI site of the
15 Bluescript vector (referred to as the Thy-I Tau 40
construct). From this recombinant vector a 10 kb, Sal
I β Not I fragment was introduced into the unique Nco
I site of the exon I of mouse Tau gene. Prior to
electroporation into the ES cells, this targeting
20 vector was linearised with Not I restriction enzyme
and gel purified. The yield of the targeting vector
was analysed both by gel electrophoresis and optical
density using an UV spectrophotometer, wherein the O.D
was measured at 260nm.

25

The loxP-PGK-hygromycin construct was cut out of the
pGEM vector by Not I and ligated into the BamHI site
of the Bluescript vector. Transformation of DH5 cells
with this 4.7kb construct yielded two positive
30 colonies out of the 20 screened. Restriction analyses
with Sal I and Sca I enzymes gave the expected bands
indicating that ligation occurred in the right
orientation which was confirmed by sequencing with the
T7 primer. The 8 kb Thy-I human Tau 40 construct with
35 the loxP site was subcloned into the SmaI site of the

above bluescript vector. After transformation 5 out of the 20 colonies screened harboured the insert. Restriction analyses using ApaI, EcorV and XmnI enzymes identified 2 colonies holding the Thy I Tau 40

5 insert in the desired orientation, additionally

~~confirmed by sequencing with primers T7 and~~
NE201(sequence located in the PGK). The next step of the synthesis of the construct involved the introduction of the 10kb Sal I β Not I fragment into

10 the unique Nco I site of the exon 1 of the mouse Tau gene. 11 colonies were screened, of which 2 were

~~found to contain the insert after transformation.~~

Sequencing using the primers NE201, NE260 (sequence located in the 5' region of mouse exon 1) and NE261

15 (sequence located in the 5' end of the PGK-hygromycin construct) was done to confirm the orientation expected and of the 2 colonies, only one had the right orientation. Figure 8 gives an overall view of the making of the construct. Restriction analyses carried

20 out using various enzymes as shown below indicated the presence of the complete construct in the right orientation. The size was estimated with the help of the 1 kb marker.

25 **ES cell culture, selection and genotyping**

The ES cell line E14 (Hooper et al., 1987) was cultured on mitomycin-treated STO fibroblasts, in Glasgow ME medium containing non-essential amino

30 acids, 20% (w/v) fetal calf serum, 0.1mM 2-mercaptoethanol and 1mM sodium pyruvate. Trypsinized ES cells ($1.5-2 \times 10^7$) were resuspended in 500 μ l of culture medium and electroporated with 10 to 15 μ g of the linearised targeting DNA, using an electric pulser

35 (Biorad Labs.) at settings of 200 V and 960 μ F in

electroporation cuvettes of 0.4 cm electrode distance. The electroporated ES cells were seeded onto mitomycin treated STO fibroblasts in 25 cm² flasks and 40 hours later, the medium was replaced with medium containing
5 100 µg/ml of Hygromycin B. Hygromycin resistant colonies were picked up 10 to 14 days later after

electroporation and further expanded for genotyping.

DNA was isolated from the selected ES cell lines and
10 10 µg was digested with the desired restriction enzyme for 4 to 6 hours. The digests were separated by

electrophoresis at 2 V/cm mechanism for 14 hours on
0.7% agarose gels resulting in an overnight run. The following day the gels were stained by Ethidium
15 bromide and photographed, processed for capillary transfer to nylon membranes. After baking and pre-hybridisation, the blot was hybridised with the
radiolabelled probes at a concentration of 2-5 x 10⁶ cpm/ml and kept overnight at 60°C. Hybridisation was
20 carried out in 6X SSC, 5X Denhardt's solution, 1% SDS, 0.1% heparine, 10% Dextran sulphate and 0.1% Salmon Sperm DNA. Membranes were washed at 60°C for one hour in 0.3X SSC, 0.5% SDS and placed for autoradiographic exposure at 70°C.

25

Genotyping by Southern blotting

For Southern blotting 10µg of genomic DNA was digested
30 for 5 hrs at 37°C and separated by electrophoresis in 0.7% agarose gels. DNA was transferred by capillary transfer to a nylon membrane with 10X SSC (1.5M sodium chloride, 150mM sodium citrate, pH 7.2). The membrane was baked for 2 hrs at 80°C, pre-hybridised for 6 hrs
35 at 60°C in 6X SSC, 4X Denhardt's solution, 1% SDS, 100

μ g salmon sperm DNA, 10% dextran sulfate and 0.05% heparin. Hybridisation was carried out overnight at 60°C in the same solution supplemented with 2-5 x 10⁶cpm/ml of the indicated [³²P]-labelled DNA probe.

5 The membrane was washed in 0.3X SSPE supplemented with 0.5% SDS for 1 hr at 60°C before autoradiographic exposure with intensifying screens at -70 C for 1-7 days.

10 Different probes were designed to genotype the ES cell lines. The ThyI-Tau-40 probe as mentioned above, ~~Hygromycin probe (a gift from Lieve Umans, Lutgarde~~
Serneels and Anton Roebroek) and a 3' probe. The latter was made by a BamHI-Kpn I restriction of a 13kb
15 EcorV-Hind III fragment harbouring exon 1 and the intron between the exons 1 and 2 of the mouse Tau gene cloned in the Bluescript vector (gift by Hirokawa,1997) yielding an external probe. The 3'
external probe thus obtained was purified from the gel
20 and used for the first screening of the electroporated ES cells cultured on Hygromycin containing selection medium. Since this probe recognised a region outside the construct, it helped us to figure out whether homologous recombination had occurred or not. (Fig.1).
25 The ThyI probe used to check the 5' region of the construct is obtained by ApaI digestion of the Thy I DNA (Prof. Van Der Putten).

Genotyping by PCR

30

Genotyping for mouse thyI-Tau40 transgenic mice by duplex PCR using the following two sets of primers:
(i) the P16 forward primer in the mouse thyI gene promoter: 5'CCCCACCACAGAATCCA in combination with
35 NE199 reverse primer in the human Tau-40 cDNA,

5'GCCCCCTGATCTTTCC3', yielding an amplicon of 135 bp;
(ii) the NE200 forward primer in the human Tau-40 cDNA
5'CTGGGGCGGTCAATAAT3' combined with the P62 reverse
primer located in the mouse thy-1 gene

5 5'CAAGGTCCCCGTTTCTCC3', producing a 213 bp amplicon.

~~The PCR programme consisted of 30 cycles of~~

denaturation at 95°C for 1 min, annealing at 60°C for
1 min and elongation at 72°C for 15 secs.

10 Western Blotting

~~Brain tissues were homogenized in 2 ml of 0.1M MES~~

Buffer pH 6.4, 0.5mM MgCl₂, 1mM EDTA, 1mM EGTA, 1mM
DTT, 0.2mM PMSF, 20mM NaF, 0.2mM Na₃VO₄, 1μM okadaic

15 acid, 5 μg/ml leupeptin, 5 μg/ml pepstatin, 5 μg/ml
soybean trypsin inhibitor, 1% sodium desoxycholate, 1%
Triton-X-100 and 0.1% SDS (Genis et al., 1995, with
minor modifications). The brain extract so obtained

was denatured at 95°C for 10 min and separated on a 8%

20 SDS-PAGE. The proteins were then transferred to
nitrocellulose membranes and after blocking, were
probed with suitably diluted monoclonal and polyclonal

antibodies. Antibodies used were HT-7 monoclonal
antibody (BR-01, clone HT-7, Innogenetics) and Tau-5
25 monoclonal antibody (60101A, Pharmigen) both diluted
1:1000.

Results

30 Thy-1 Tau 40

Expression of the human Tau 40 cDNA in the brain of
transgenic mice was obtained using the Thy-1 promoter.
Ten injection sessions yielded 46 pups (from 450

35 injected FVB oocytes transferred into 17 F1

pseudopregnant females). Genotyping by Southern blotting technique identified 5 out of the 46 pups as the human-Tau 40 founders (Figure 2). Additional genotyping using duplex PCR identified these five mice

5 as founders. The F1 offspring of the founder Thy-1

~~Tau 40/4 suffered from premature death and the~~

complete strain died out within 2 months. Founder

Thy-1 Tau 40/3 failed to reproduce normally and as a result three founder lines survived and appear

10 "genetically" healthy. The Western results showed a ± 70 kDa Tau protein in all the transgenic lines

~~(Figure 3) representing the longest human Tau isoform~~

The transgene expression of all the founder lines

reached comparable levels with this relation of Line 1

15 showing the highest expression, followed by Line 2

closely and then Line 5. The strain of Thy-1 Tau 40/5 is being bred into homozygous strains.

PAC2 human Tau gene clone

20

The purified PAC2 clone was characterised by the analyses of restriction fragments separated by Pulse Field Gel Electrophoresis (PFGE) and identified by Southern blotting using the probes generated by PCR

25 (see materials and methods). The results of the different digestions using rare-cutting restriction enzymes are shown on the restriction map of the human Tau gene (Figure 4). The PAC2 clone as sized by PFGE was around 200 kb and housed the entire human Tau

30 gene, confirmed by Southern blotting using different probes that identified the 5', middle and 3' regions of the gene. To mention a few of the enzymes that

were used to linearise the construct outside the Tau gene, we found that restriction with Sall and NotI
35 enzymes gave 4 and 5 bands respectively, while PmeI

cleaved the gene twice and Cpo1 linearised the clone
(Figure 5). The double digests of the PAC2 DNA of
NotI and Sall with Cpo1 analysed on the PFGE
demonstrated that one of the fragments made by the
5 single digests of the NotI and Sall enzymes was
~~cleaved but the Southern blotting done demonstrated~~
that Cpo1 did not cleave any part of the human Tau
gene. These analyses helped us to conclude that the
PAC2 DNA could only be linearised by Cpo1 without
10 fragmentation of the human Tau gene.

~~The linearised DNA was then purified using Qiagen~~
columns and dialysis chambers [Millipore Purification
columns, Spectra PorCE Dispodialyzer of Spectrum] of
15 different pore sizes, of which we found the tip-20
column of QIAGEN the most efficient as it yielded DNA
with least shearing and with a low elution volume a
concentration of 1 ng/ μ l was obtained, (one of the
drawbacks of the dialyses membranes) which is required
20 for microinjection. Genotyping by PCR identified 2
out of 9 pups as the PAC2 human Tau gene founders.
Although the PCR did show us results yet no expression
was observed in these mice as studies by Western
Blotting.

25

Knockin-Knockout targeted vector

The loxP-PGK-hygromycin construct was cut out of the
pGEM vector by NotI and ligated into the BamHI site of
30 the Bluescript vector. Transformation of DH5 α cells
with this 4.7kb construct yielded two positive
colonies out of the 20 screened. Restriction analyses
with Sall and Scal enzymes gave the expected bands
indicating that ligation occurred in the right
35 orientation which was confirmed by sequencing with the

T7 primer. The 8 kb Thy-1 human Tau 40 construct (see materials and methods) with the loxP site was subcloned into the SmaI site of the above bluescript vector. After transformation 5 out of the 20 colonies screened harboured the insert. Restriction analyses using ApaI, EcorV and XmnI enzymes identified 2 colonies holding the Thy 1 Tau 40 insert in the desired orientation, additionally confirmed by sequencing with primers T7 and NE201 (sequence located in the PGK). The next step of the synthesis of the construct involved the introduction of the 10kb SalI - NotI fragment into the unique NcoI site of the exon 1 of the mouse Tau gene. 11 colonies were screened, of which 2 were found to contain the insert after transformation. Sequencing using the primers NE201, NE260 (sequence located in the 5' region of mouse exon 1) and NE261 (sequence located in the 5' end of the PGK-hygromycin construct) was done to confirm the orientation expected and of the 2 colonies, only one had the right orientation. Figure 8 gives an overall view of the making of the construct. Restriction analyses carried out using various enzymes as shown below indicated the presence of the complete construct in the right orientation (Figure 9). The sizes have been estimated with the help of the 1 kb marker.

Enzymes Band sizes as seen in the insert with the
right orientation

	ApaI	~9.2kb, ~6.6kb, ~0.8kb
5	BamHI	~0.2kb, ~0.4kb, ~0.7kb, ~0.9kb, 4.9kb, ~9.5kb
<hr/>		
	EcoRI	~3.0kb, ~3.4kb, 0.9kb, ~8.0kb, 0.7kb
	KpnI	~6.5kb, ~7.0kb, ~2.9kb
	NdeI	~13.5kb, ~1.2kb, ~1.6kb
10	NslI	~10.9kb, ~5.4kb
	SacII	~5.2kb, ~3.4kb, ~7.7kb
<hr/>		
	ScaI	~8.7kb, ~2.5kb, ~5.2kb
	SmaI	~3.4kb, ~8.1kb, ~4.4kb, 0.2kb
	XbaI	~8.7kb, ~2.4kb, ~3.4kb, ~0.6kb, ~1.2kb

15

Figure 10 shows a restriction map of the concluded
construct. This final construct was linearised with
NotI and purified on a tip-100 column (Qiagen) which
finally gave a concentration of 2.25 $\mu\text{g}/\mu\text{l}$ of which 8
20 μl was used for electroporation into ES cells. The ES
cells that survived the electroporation were grown on
Hygromycin selective medium and after a fortnight
well-grown 333 colonies had been picked up for
culturing. With the help of Southern blotting using
25 the external 3' probe for the first screening (as
mentioned in the materials and methods), we were able
to pick up 6 potential positive cell lines in the
first screening. After the second screening of these
6 colonies with the internal Hygromycin and ThyI Tau
30 40 probe we obtained one cell line that contained the
right targeted construct in it. Besides, the ThyI
probe used finally also confirmed the presence of the
5' region of the construct in the positive cell line
(Figure 11) and the 5' BamHI fragment hybridising with
35 this probe measured the same number of base pairs as

the predicted BamHI-fragment if the construct was homogenously recombined. The marker used in the blots is a 1 kb marker.

5	Probes	Digestion of ES DNA	Band Size	Homologous Recombination	Type of Probe
	3'	KpnI	11.2kb	HR ₁	External probe
			8.4kb	No HR	
10	Hygromycin	KpnI	11.2kb	HR	Internal probe
		BamHI	7.9kb	HR	Internal probe
	ThyI Tau 40	KpnI	7.6kb		Internal probe
	ThyI	BamHI	8.9kb	HR	Internal probe

15 This first positive cell line was used for injection into blastocysts while further screening has resulted in five more potential cell lines. Uterine transfers have so far given 20 pups from three female mice of which 6 are chimeric.

CLAIMS

1. A nucleic acid vector comprising:

(a) a nucleic acid sequence encoding a human Tau
5 protein;

~~(b) a sequence capable of directing expression~~
of said human Tau protein in the nervous
system of a non-human animal; and

(c) a targeting sequence which facilitates
10 integration of said vector into the genome
of said animal so as to prevent expression
~~of equivalent Tau protein or a related or~~
equivalent protein from said animal in
favour of said human Tau protein.

15 2. A vector according to claim 1 further comprising
a sequence encoding a reporter molecule.

20 3. A vector according to claim 2 wherein said
reporter molecule comprises the hygromycin Pgk-hyg
marker gene sequence.

25 4. A vector according to any of claims 1 to 3
wherein said sequence encoding human Tau is a cDNA
sequence.

5. A vector according to claim 4 wherein said cDNA
sequence encodes a Tau 40 isoform.

30 6. A vector according to any preceding claim wherein
said sequence capable of directing expression of said
human Tau protein is a mouse promoter.

35 7. A vector according to claim 6 wherein said mouse
promoter is a Thy-1 promoter.

8. A vector according to claim 7 wherein said targeting sequence comprises a nucleotide sequence exhibiting a sufficient degree of homology with said sequence encoding said equivalent Tau protein in said animal or flanking sequences thereof, to facilitate integration of said vector into the genome of said animal by homologous recombination.
9. A vector according to claim 8 wherein said targeting sequence comprises a NcoI restriction site corresponding to the unique NcoI restriction site of exon1 of the mouse wild type genome.
10. A vector according to any of claims 1 to 9 further comprising two loxP sites flanking either of the sequences of step (a) and (b).
11. A vector according to any of claims 1 to 9 further comprising a stop sequence capable of preventing expression of said human Tau protein and which sequence is flanked by two loxP sites capable of undergoing reciprocal conservative DNA recombination in the presence of Cre recombinase with the resulting excision of said stop sequence.
12. A nucleic acid vector comprising:
- (a) a nucleic acid sequence encoding a human protein capable of modulating human Tau protein;
 - (b) a sequence capable of directing expression of said protein in the nervous system of said animal; and
 - (c) a targeting sequence capable of facilitating integration of said vector into the genome of said animal optionally at a position

corresponding to a sequence in said animal
encoding an equivalent of said human protein
so as to prevent expression of said
equivalent sequence in favour of said human
5 protein capable of modulating human Tau
protein.

13. A vector according to claim 12 wherein said human
10 protein is capable of phosphorylating a human Tau
protein.

14. A vector according to claim 12 or 13 wherein said
human protein is GSK-3 β kinase.

15

15. A vector according to any of claims 12 to 14
wherein said nucleic acid sequence in step a) is a
cDNA sequence.

20 16. A vector according to any of claims 12 to 15
wherein said sequence capable of directing expression
of said protein capable of modulating human Tau
protein is a mouse promoter.

25 17. A vector according to claim 16 wherein said
promoter is a Thy-1 promoter.

18. A vector according to any of claims 12 to 16
further comprising two loxP sites flanking either of
30 the sequences of step (a) and (b).

19. A vector according to any of claims 12 to 17
further comprising a stop sequence capable of
preventing expression of said protein capable of
35 modulating human Tau protein, and which stop sequence

is flanked by two loxP sites capable of undergoing reciprocal conservative DNA recombination in the presence of Cre recombinase with the resulting excision of the stop sequence.

5

20. A host cell transformed, transfected or injected with a vector according to any one of the preceding claims.

10 21. A host cell according to claim 20 wherein the cell is a non-human animal cell.

22. A host cell according to claim 21 wherein said non-human animal cell is a non-human mammalian embryo
15 cell.

23. A host cell according to claim 22 wherein said cell is an embryonic stem cell.

20 24. A method of making a transgenic non-human animal comprising the steps of:

- (a) introducing into an embryo cell of said animal a nucleic acid vector according to any of claims 1 to 19;
- 25 (b) introducing the embryo from step (a) into a female animal;
- (c) sustaining the female in step (b) until such time as the embryo has sufficiently developed and is borne from the female; and
- 30 (d) sustaining the transgenic animal.

25. A method according to claim 24 wherein said vector is introduced firstly into an embryonic stem cell which is subsequently introduced into a
35 blastocyst of said animal.

26. A method according to claim 25 wherein both of the vectors encoding said human Tau and said protein capable of modulating human Tau according to claims 1 to 11 and 12 to 19 respectively are introduced into
5 said stem cell.

27. A method according to any of claims 24 to 26 wherein said non-human animal is a mammal.

10 28. A method according to claim 27 wherein said mammal is a mouse.

29. A method according to claim 24 or 25, comprising the step of introducing a vector according to any of
15 claims 1 to 11 into a first animal and a vector according to any of claims 12 to 19 into a second animal, crossing said first and second animals and selecting among the progeny those that express both said human Tau and said protein capable of modulating
20 human Tau protein.

30. A method of making a transgenic non-human animal, which expresses a human Tau protein comprising the steps of:

- 25 (a) introducing sequentially or simultaneously into an embryo cell of said animal a first nucleic acid vector comprising a transgene capable of expressing said human Tau protein in the nervous system of said animal and a
30 second nucleic acid vector comprising a sequence of nucleotides which upon integration into the genome of said animal is capable of preventing expression of endogenous Tau protein from said animal;
- 35 (b) introducing the embryo from step (a) into a

female animal,

(c) sustaining the female in step (b) until such time as the embryo has sufficiently developed and is borne from the female; and

5 (d) sustaining the transgenic animal.

31. A method according to claim 30 wherein each of said first and second nucleic acid vectors are introduced in the same embryo cell.

10

32. A method according to claim 30 or 31 wherein said transgenic non-human animal is a mammal.

15 33. A method according to claim 32 wherein said mammal is a mouse.

20 34. A method according to any of claims 30 to 33 wherein said second nucleic acid vector comprises a sequence of nucleotides comprising a region of homology with a sequence encoding an equivalent Tau protein in said animal or with a region flanking or adjacent said sequence so as to facilitate integration of said vector into the genome of said animal by homologous recombination.

25

30 35. A method of generating a transgenic non-human animal which is a model for Alzheimers disease or related neurodegenerative disorders, comprising the steps of crossing a first transgenic non-human animal comprising a vector according to any of claims 1 to 11 in its genome with a second transgenic non-human animal comprising a vector according to any of claims 12 to 19 in its genome selecting among the progeny those that express both human Tau protein and said
35 kinase.

36. A method according to claim 35 wherein said nucleic acid vector in said first transgenic animal comprises a vector according to claim 10 or 11.

5 37. A method according to claim 36 wherein said second transgenic animal comprises a vector according to any of claims 12 to 19.

10 38. A method according to claim 34 which further comprises introducing into said second animal a vector comprising a transgene encoding Cre recombinase.

15 39. A transgenic non-human animal obtainable according to the methods of any of claims 24 to 38.

40. A transgenic non-human animal that is a model for neurodegenerative disorders, comprising:

- 20 (a) an introduced DNA sequence encoding and capable of expressing the protein Tau in the nervous system of the animal; and
- (b) a DNA sequence encoding and capable of expressing a protein capable directly or indirectly of modulating Tau protein.

25 41. A transgenic non-human animal according to claim 40 wherein said sequence in step (a) comprises a vector according to any of claims 1 to 11.

30 42. A transgenic non-human animal according to claim 40 wherein said sequence according to step (b) comprises a vector according to any of claims 12 to 19.

35 43. A method of identifying a compound which modulates human kinase mediated phosphorylation of

human Tau protein which method comprises administering
a test compound to a non-human animal according to an
of claims 39 to 42 expressing both said human Tau
protein and said human kinase and monitoring the
5 phosphorylation profile of said Tau protein compared
to one of said transgenic animals which has not been
administered with the compound.

44. A compound obtainable according to the method of
10 claim 43.

45. A pharmaceutical composition comprising a
compound according to claim 44 together with a
pharmaceutically acceptable carrier, diluent or
15 excipient therefor.

46. Use of a compound according to claim 44 in the
manufacture of a medicament for the treatment of
neurodegenerative disorders.

20 47. Use according to claim 46, wherein said
neurodegenerative disorders comprise any of FTDP-17
(Fronto-temporal dementia associated with Parkinson's
disease), Cortico-basal degeneration, progressive
25 supranuclear palsy, multiple system atrophy, Pick's
disease, Dementia Pugilistica, Dementia with tangles
only, dementia with tangles and calcification, Down
syndrome, Myotonic dystrophy, Niemann Pick's disease
type C, Parkinsonism-dementia complex of Guam,
30 Postencephalic Parkinsonism, Prion diseases with
tangles, subacute sclerosing panencephalitis.

48. A method of treating neurodegenerative disorders
mediated by phosphorylation of human Tau protein
35 comprising administering to a patient a compound as

defined in claim 44 or a composition according to claim 45.

5 49. A method of generating a transgenic non-human animal which is a model for Alzheimers disease or related neurodegenerative disorders, comprising the steps of crossing a first transgenic non-human animal comprising a vector having, i) a nucleic acid sequence encoding a human Tau protein, ii) a sequence capable
10 of directing expression of said human Tau protein in the nervous system of said animal and iii) a targeting sequence which facilitates integration of said vector into the genome of said animal, with a second transgenic non-human animal comprising a vector
15 according to claim 12, selecting among the progeny those that express both human Tau protein and said protein capable of modulating Tau protein.

20 50. A method according to claim 49 wherein said vector in said first and/or said second transgenic non-human animal comprises a stop sequence capable of preventing expression of said human Tau protein or said protein capable of modulating Tau protein which sequence is flanked by two loxP sites capable of
25 undergoing reciprocal conservative DNA recombination with the resulting excision of said stop sequence.

51. A transgenic non-human animal obtainable according to the method of claim 49 or 50.
